PART C. SUMMARY OF AIR POLLUTANT EMISSIONS IN INTERSTATE AQCRs 7

ABSTRACT

This report summarizes annual cumulative estimates of source emissions of five criteria pollutants: particulates, sulfur oxides, nitrogen oxides, volatile organic compounds, and carbon monoxide. Source emissions data are reported to the U.S. Environmental Protection Agency under provisions of Section 110 of the Clean Air Act, as amended in 1977, and of EPA Regulations, Title 40, Code of Federal Regulations, Part 51.321. Summary data are presented for the Nation as a whole, for individual States, for intrastate and individual interstate portions of Air Quality Control Regions, and for total interstate Air Quality Control Regions.

The data compilations presented result from the operations of the National Emissions Data System (NEDS), which functions as a component of the comprehensive EPA air information system, the Aerometric and Emissions Reporting System (AEROS). AEROS is managed by the National Air Data Branch, Monitoring and Data Analysis Division, Office of Air Quality Planning and Standards, U.S. Environmental Protection Agency, Research Triangle Park, North Carolina.

ACKNOWLEDGMENT

The National Emissions Report series is the result of the generous cooperation and diligent efforts of personnel in many areas of government and private industry. Their contributions are gratefully acknowledged.

1981 NATIONAL EMISSIONS REPORT

Introduction

This report summarizes, by source category, estimates of emissions in 1981 of those air pollutants for which national standards have been promulgated. These pollutants, which are called criteria pollutants, are particulates, sulfur oxides (SO_x), nitrogen oxides (NO_x), volatile organic compounds (VOC), and carbon monoxide (CO). National Emission Reports, which are a series of annual reports, are compiled from information contained in the National Emissions Data System (NEDS) on emission sources. Compilations of emissions data are presented for the Nation as a whole, for individual States, for intrastate Air Quality Control Regions (AQCRs), for respective State portions of interstate AQCRs, and for interstate AQCRs. Figure 1 is a map illustrating AQCR boundaries.

This report represents the best available indicators of national emissions for the calendar year 1981. Table 1 shows EPA-calculated national emissions estimates that are independent of NEDS data for 1981. Readers interested only in national emissions estimates should refer to this table for total national emissions and national emissions for major source category groupings. More detailed emissions summary reports for the Nation, each State, and AQCR, based on NEDS data, are given in Parts A, B, and C, the body of the report. The estimates reported are based on point source records contained in NEDS as of July 1983. State-submitted Annual Reports that were successfuly updated to NEDS files prior to this date are included. Thus, the data are generally comparable to data collected for the development of State Implementation Plans (SIPS), but include revisions and updating information where they are available. The following text sections provide a detailed technical description of the procedures that were used to develop the emissions data.

Emissions Inventory

Much detailed information concerning sources and their operations is needed for the development of the emissions inventory by which the impact of source emissions on an area's air quality can be assessed at the State or local level. The NEDS, operating through the EPA Office of Air Quality Planning and Standards (OAQPS), processes source and emissions information for the entire Nation. Since NEDS operations were initiated in 1971, the National Air Data Branch (NADB) of OAQPS and EPA Regional Offices have been engaged actively in the collection and analysis of air pollutant emissions data. A detailed description of the NEDS and of its methodology for compiling an emissions inventory is available in OAQPS Guideline AEROS Manual Series, Volume II: AEROS User's Manual (EPA-450/2-76-029). Brief discussions of the NEDS basic elements, used for the preparation of the National Emissions Reports, are given below.

NEDS Point-Source File

The NEDS point-source file contains data concerning stationary facilities that are individual emitters of relatively large quantities of one or more air contaminants. A point source is defined for State reporting purposes as a facility at which the annual emissions of any one criteria pollutant equal or exceed 100 tons (90.7 metric tons) per year. For carbon monoxide the minimum size for reporting is 1000 tons (907 metric tons) per year. Nearly all point source data originate at State air pollution control agencies. In general, individual emission points are defined within facilities to represent the emissions from individual stacks and processes. There may be emitting points at a facility that individually have emissions of fewer than 100 tons per year, but emissions from such points are included in NEDS if the criterion of emissions of 100 tons per year for the entire facility is met. Data for other facilities, regardless of emissions, may also be included if the data are reported from State files.

At the time of this report, NEDS contains data from approximately 230,000 emitting points at 55,000 facilities in all States, the District of Columbia, and three territories. Considerable information is stored for each point source. For example, NEDS stores data on annual operating rates, or activity levels, of a process. More specifically, these rates may relate to the amount of fuel consumed by a boiler, quantity of product manufactured in an industrial process, or some comparable measure. Information identifying existing air-pollution control devices and their efficiencies is also recorded. These and similar data are used to determine source emissions according to the procedures outlined in the following discussion of the NEDS emission factor file.

NEDS point-source data are reviewed continually through extensive and cooperative efforts by the National Air Data Branch, the EPA Regional Offices, and the State and local air-pollution control agencies. Under provisions of the Clean Air Act and SIP requirements, State agencies must submit revised source data in NEDS format to EPA annually for (1) each source achieving final compliance with an SIP emission limitation regulation or strategy, (2) each new or modified source receiving approval to begin construction or operation, and (3) each source that terminated operations during a reporting period. Thus, the basic data of the NEDS are revised and updated periodically and reflect progress under the SIPs.

The point source file contains the data reported to NEDS by the State air pollution control agencies. Some States still rely on manual procedures for maintenance of their own source/emissions files. The majority of States have, however, installed, or are in the process of installing automated data systems and EPA has assisted many of the States in these efforts. The most common system in use is one designed and maintained by EPA: the Emission Inventory System/Point Source of the Comprehensive Data Handling

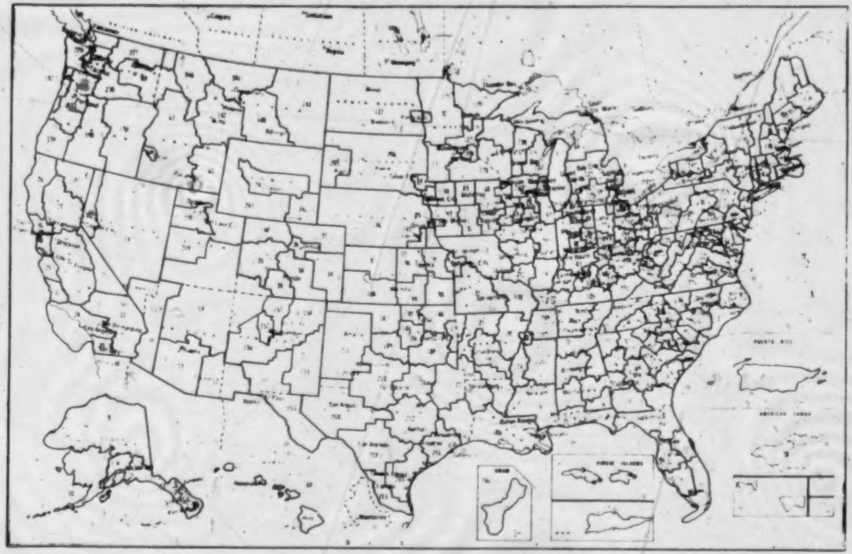

Figure 1. Air Quality Control Regions.

Table 1. EPA-CALCULATED NATIONAL EMISSIONS ESTIMATES FOR 1981

Source Category	Emissions estimates, 10^3 tons/year				
	Particulates[1]	Sulfur oxides	Nitrogen oxides	Volatile organics	Carbon monoxide
Fuel Combustion (point and area)	2,740	19,630	11,060	2,120	6,860
Residential	950	210	410	1,930	5,830
Electric generation	1,220	16,210	7,120	50	330
Industrial	500	2,590	3,250	130	640
Commercial-institutional	70	620	280	10	60
Industrial processes (point)	3,100	4,190	720	7,870	6,480
Chemical manufacturing	100	610	210	1,750	2,210
Food/agriculture	580	0	0	200	0
Primary metals	450	2,110	70	80	1,900
Secondary metals	90	30	0	0	320
Mineral products	1,670	670	180	0	30
Petroleum industry	50	650	230	1,440	1,230
Wood products	160	120	30	0	790
Organic solvent evaporation	0	0	0	3,450	0
Petroleum storage/transport	0	0	0	880	0
Other processes	0	0	0	70	0
Solid waste disposal (point and area)	400	30	100	710	2,330
Government	50	10	10	20	170
Residential	290	10	70	640	1,870
Commercial-institutional and Industrial	60	10	20	50	290
Transportation (area)	1,490	1,000	10,740	7,000	60,080
Gasoline vehicles	870	250	5,880	5,800	56,140
Light duty vehicles	600	160	3,810	3,570	31,690
Light duty trucks	170	60	1,260	1,170	9,070
Heavy duty vehicles	80	20	660	580	10,240
Motorcycles[2]	10	0	10	90	250
Off-highway	10	10	140	390	4,890
Diesel vehicles	510	470	4,530	550	1,290
Light duty vehicles	20	10	30	10	20
Heavy duty vehicles	340	270	2,840	220	720

Aircraft	80	10	120	180	1,060
Vessels	30	270	210	470	1,590
Miscellaneous (area)	1,040	10	210	3,420	7,090
Forest fires	500	10	120	570	4,150
Forest managed burning	400	0	80	280	2,230
Agricultural burning	80	0	10	70	500
Structural fires	60	0	0	40	210
Gasoline station evaporation loss	0	0	0	930	0
Solvent evaporation loss	0	0	0	1,530	0
Grand total (point and area)	8,770	24,860	22,830	21,120	82,840

[1] Does not include area source fugitive dust emissions from paved roads, unpaved roads, and unpaved airstrips.

[2] Highway motorcycle emissions are not included in NEDS summaries.

System (CDHS). EIS/PS has the capability to output data in NEDS format for reporting to EPA. A number of systems designed and maintained by the States also have a similar capability. Data can be easily reported to NEDS by means of data format conversion programs.

NEDS Area Source File

In NEDS, area sources are all emissions sources not identified as point sources. For example, the NEDS area source file contains data on all mobile sources such as motor vehicles, aircraft, and railroads; small stationary sources; and miscellaneous sources such as forest fires, agricultural burning, and retail gasoline marketing operations. Unlike data for point sources, however, data for each of these small individual sources are not stored in NEDS. Rather, estimates of total emission levels for specific categories of area sources are stored for individual geographic areas. Generally, data relevant to area source emissions (for example, total amount of gasoline consumed by all motor vehicles) are grouped for each of the approximately 3100 counties or county equivalents in the United States. Area-source data are developed primarily from reports published by other Federal agencies and, when possible, from valid data collected by State air-pollution control agencies. Detailed procedures for the determination of levels of area source activity are discussed in AEROS User's Manual, Volume II (OAQPS No. 1.2-039), EPA-450/2-76-029. Under current SIP requirements, States are not required to submit area-source data to EPA. Therefore, area source data are updated annually by NADB; States are given the opportunity, however, to review the EPA-generated area source data for accuracy and completeness. In addition, a number of State agencies have voluntarily submitted their own area source data for inclusion in NEDS. These data are reviewed for consistency with the NEDS point source data and are added to the NEDS file if they are acceptable for inclusion.

NEDS Emission-Factor File

In normal NEDS operations, source emissions are calculated automatically via computer program, based on the data stored in point and area source files. The principal vehicle for these calculations is the NEDS emission factor file. An emission factor is a statistical average--a quantitative estimate--of the rate at which a pollutant is released to the atmosphere (as a result of an activity such as combustion or industrial production) divided by the level of that activity. Thus, an emission factor relates the quantity of pollutants to an indicator of activity such as production capacity or quantity of fuel burned. Because emission factors are statistical averages, they are not necessarily precise indicators of emissions from an individual source. When they are applied to a large number of sources, however, a reasonable estimate of total emissions can be obtained. In general, the larger the sample, the lower the percentage of error. Therefore, for the entire Nation, an emission estimate based on emission factors may be quite precise, but for smaller geographic areas the percentage of error increases. Emission factors are usually determined from results of source tests in which quantities of air pollutants are measured from specific processes. Emission factors may also be determined from process material balances and engineering appraisals of particular processes. A collection of derived emission factors is given in Compilation of Air Pollutant Emission Factors (U.S. Environmental Protection Agency, Research Triangle Park, N.C., Publication No. AP-42, March 1975) and its supplements.

The emission factors in AP-42 and associated data maintained by NADB are related to the activity levels for sources covered by NEDS. Area source emission factors are designated for each area source category represented in NEDS. The emissions are determined by multiplying the appropriate emission factor by the activity level recorded.

Similarly, point source emission factors are related to point source activity levels through the NEDS Source Classification Code (SCC), determined and recorded for each point source. These codes give specific identification of the source (e.g., industrial coal-fired boiler, solid waste incinerator, gray iron cupola) and define the units of the activity level recorded in the point source file. Appropriate emission factors are designated for each SCC and are multiplied by the activity level to calculate the emissions. Where a control device is indicated in the point source file the given control device efficiency is included in the emission calculation so that estimated actual emissions are computed for all sources. Additionally, provision is made for the direct recording of emissions determined by stack tests or engineering material balances for specific sources. It is assumed that the determination of emissions by these latter methods provides a more precise estimate than the calculation of emissions by the application of an emission factor. Further, when the point source file indicates that the recorded emissions estimates were determined by a source test or material balance, the computer program that calculates emissions will substitute these data for emissions estimates that were calculated through the use of factors.

Some SCCs do not have corresponding emission factors in the NEDS emission factor file. These SCCs are general in nature (i.e., termed miscellaneous or unspecified) and are used for the categorization of point sources that are otherwise not classifiable. A source will fall in these categories when (1) no emission information is available, (2) the source is inadequately identified, or (3) the source is unique, or very unusual, and therefore cannot be assigned a specific SCC.

For some of the sources in such miscellaneous categories, emissions estimates may be derived by engineering analysis or judgment. The resulting emissions estimates are incorporated into the point source file and carry the same weight as calculated emissions estimates. The National Emissions Reports are based on all emissions estimates in the NEDS point source file, however derived.

The error caused by having no estimates for some point sources and "guess" estimates for a few others is insignificant when emissions are summarized for the Nation as a whole; but that error may be fairly sizable for local areas in which a number of point sources could not be assigned a specific SCC. The evidence suggests that the problem of missing emissions estimates for a few point sources is not major when considered in relation to (1) the potential imprecision introduced through an application of emission factors to specific point sources, and (2) the imprecision introduced through the calculation of area source activity levels for small geographic areas.

Reliability of Reported Emissions

Because an emissions inventory such as NEDS is often used as a basis for making important management decisions, it is imperative that the data therein be as accurate and precise as possible. Hence, when an inventory is developed, the question of reliability must be considered if the resulting emissions estimates are to be applied with any confidence.

Imprecision of emissions data is an inevitable result of the estimation techniques used to develop the data base, though these techniques are, for practical considerations, the best that are available. As noted previously, the use of emission factors and calculation of area source activity levels for NEDS cause inherent variations, or random errors, in the calculated emissions. Generally, as the number of observations on which emissions estimates are based is increased, the impact of imprecision of the data decreases. Thus, for the NEDS national emissions summary tabulation, which is based on a very large number of observations, imprecision is a relatively minor factor. For emissions summaries for smaller geographic areas (such as States and AQCRs), which are based on a smaller number of observations, the error potential increases.

Other factors that influence emissions inventory reliability are mistakes and biases in the reported data. Major mistakes input to NEDS are prevented by edit programs used to process input data or by review of NEDS output reports prior to publication of the National Emissions Report. Such data errors have been corrected for this report. It is likely that there are a number of other, relatively minor mistakes that remain that probably have an insignificant impact on the overall reliability of reported emissions. Biases in the NEDS data are introduced as a result of inaccuracies, or deficiencies, in the techniques used to compile the data. In comparison with mistakes, biases usually represent a more subtle type of error because it is rarely apparent with biases that the resulting emissions estimates deviate from what the "true" values should be (as is often the case with many mistakes). As an example, the emissions from a source may be measured by a sampling technique that yields biased results. Another example is the use of a biased (i.e., nonrepresentative) emission factor to estimate the emissions from a number of sources.

For NEDS, biases are introduced principally through inaccuracies in the procedures used to compile NEDS area source data and lack of complete and timely reporting of point source data by State agencies. In addition, the regulation prescribing reporting or point source data (40CFR 51.321) includes an inherent bias since it requires reporting only from facilities identified as emitting over 100 tons per year. Emissions from fuel combustion not accounted for by point sources are included instead as area source fuel use, but with less precision than if all fuel use were accounted for by individual point sources. Emissions from industrial process sources not reported as point sources are not accounted for, however. Thus, NEDS data may be biased low for industrial process emissions in cases where State agencies fail to report all major industrial process sources adequately as point sources or where emissions from facilities individually emitting less than 100 tons per year are collectively significant.

As a possible means of checking the reliability of NEDS emissions data, Table 1 shows EPA-calculated national emissions estimates for each of the five criteria pollutants according to the same major source categories as defined in the NEDS emissions summaries. These data are obtained from the data prepared for the report National Air Pollutant Emission Estimates, 1940-1982 (EPA-450/4-83-024). The methodology used to derive these data relies upon essentially the same sources of information for emission factors and area source calculation algorithms as used with NEDS. Differences between NEDS area source data and totals reported in Table 1 are due primarily to the differences in the precision and the detail of the methods of calculation. For NEDS, national emissions totals are obtained by summarizing individual county area source emissions. National Trends Report emissions totals are obtained from one calculation performed at the national level by use of total national activity levels and national average emission factors for each source category. For source categories reported in NEDS as point sources, national emissions totals reported in Table 1 below are also based on one calculation, performed at the national level; in this calculation, use is made of available data on national industrial production and fuel consumption, other appropriate data, and national average emission factors. Where necessary, average level of pollution control is considered to estimate actual emissions. The methodology for EPA calculation of national emissions estimates is inherently less precise than that used to produce NEDS summaries. It does not allow inclusion of emissions for individual sources based on estimation methods that may be more accurate than a standard emission factor calculation. The national calculation does not suffer from biases and omissions of sources to the same extent as NEDS point source data, however. As a result, the national emissions totals presented in Table 1 are judged to be the most reliable estimates of national emissions available at the time of this report. EPA national emissions estimates are periodically revised as better emission inventory techniques and emission factors are developed. Updated national emissions estimates for 1981 will be presented in future editions of National Air Pollutant Emission Estimates.

Comparison of the national NEDS emissions totals with EPA-calculated national emissions estimates indicates reasonable agreement for most source categories. Notable discrepancies do exist in some cases, however. Some of these can be clearly traced to specific deficiencies in the NEDS data. Others involve more complex problems concerning differences in techniques used to produce the data. It is difficult to resolve these problems without an exhaustive review of NEDS data.

For stationary fuel combustion sources, most emission totals are in close agreement except for the industrial sector. NEDS totals are all higher than Table 1 values for industrial fuel use. The factor that contributes most to this discrepancy is that NEDS data are out of date for some States. For fuel oil combustion, NEDS point source fuel use and emissions are substantially higher than what would be expected in 1981. In recent years U.S. fuel oil consumption has decreased greatly but because of the delay in reporting by States this change has not been adequately reported in NEDS. For electric utilities, NEDS fuel use is very close to values reported by the U.S. Department of Energy, but NEDS emissions of SO_2 and NO_x are slightly higher than in Table 1. For SO_2, NEDS emissions are about 6% higher. This is probably due to differences in sulfur contents and emissions calculated by procedures other than standard emission factor calculations in the point source data reported by States. For NO_x, NEDS emissions are about 12% higher than in Table 1. This is due to the use of outdated Source Classification Codes in NEDS that do not adequately represent tangentially fired boilers that have typically lower emissions than other boilers of the same size.

Total industrial process emissions in NEDS and Table 1 are comparable except for VOC, for which NEDS is much lower. The emissions for individual industrial process categories also generally agree except as discussed below. For particulate, most NEDS categories have slightly lower emissions than Table 1 values. This occurs primarily because (1) plants emitting less than 100 tons/year may not be included in NEDS, and (2) some emission points for the facilities in NEDS may not be properly represented. The latter problem primarily relates to industrial process fugitive emission points, for which emission factors and emission estimating techniques are frequently not known by State and local agencies responsible for reporting NEDS data. The NEDS particulate emissions for the chemical industry are much higher than in Table 1. This results primarily from apparently erroneous data reported by a few States. For SO_2 and NO_x, NEDS emissions from process heaters in the petroleum industry are too high, either because the NEDS data are out of date or were erroneously reported by States. For VOC, the emissions in many categories are much lower in NEDS than in Table 1. For chemical manufacturing, this appears to result from a lack of reporting of fugitive emissions sources in NEDS. Emissions for all chemical processes are not accurately known, however, so that the Table 1 value could be unrealistically high. For food/agriculture, many vegetable oil refining plants are apparently missing from NEDS. For the petroleum industry, fugitive emissions in petroleum refineries and other fugitive emissions associated with crude oil production are poorly represented in NEDS. Emissions for these processes are not accurately known, either, so that Table 1 values could be unrealistically high. Finally, the emissions for industrial process organic solvent evaporation are much lower in NEDS than in Table 1. This occurs because many small sources of organic solvent emissions are apparently not included in NEDS as point sources. However, emissions from these sources are accounted for instead as area sources and are included in the category "solvent evaporation loss" under miscellaneous area sources. As a result, the sum of point and area source organic solvent use in NEDS and in Table 1 is approximately the same.

For highway vehicles, NEDS emissions of NO_x, VOC and CO are significantly different from the data shown in Table 1. In addition, particulate emissions are different because, as noted in Table 1, reentrainment of dust from paved roads is not included. Table 1 particulate emissions include only emissions from vehicle exhaust and tire wear. National NEDS emissions of NO_x are about 14% lower than Table 1, while NEDS VOC emissions are about 20% higher and CO emissions are about 34% higher for highway vehicles. These differences result from a difference in the procedure used to calculate the estimated emissions. For the data in Table 1, emissions are calculated using national data for vehicle-miles travelled (VMT), which have been disaggregated into different road categories corresponding to assumed average vehicle speeds of 55, 45 and 19.6 miles per hour. For NEDS, adequate county level data to develop this split in VMT have been available for only a small number of States. As a result, all of the NEDS data have been calculated using a procedure that splits VMT into only two portions corresponding to 45 and 19.6 mile per hour average speeds. The effect of this procedure is that in NEDS VMT at the 19.6 mile per hour speed are overestimated causing the discrepancies in emissions noted above, since highway vehicle emission factors for NO_x, VOC and CO are highly dependent upon vehicle speed. It is recognized that a better procedure for use in NEDS is needed. Implementaiton of such an improved procedure is dependent upon the availability of the resources required to develop such a methodology and provide for the annual updating of data. During the next fiscal year it is hoped that a plan can be developed to move toward this goal.

Fugitive Dust Sources

The NEDS National Emissions Report includes, estimated particulate emissions from area sources of fugitive dust. Estimated emissions from vehicle travel on unpaved roads and aircraft operations on unpaved airstrips are included as miscellaneous sources. Estimated emissions from entrainment of dust from paved roads are included with highway vehicle particulate emissions. Source categories are also defined for construction, land tilling, and miscellaneous wind erosion. No emissions are reported for these categories due to lack of suitable emission factors and NEDS source inventory techniques. The emission estimates for unpaved roads and entrainment of dust from paved roads should be regarded as rough, order of magnitude emission estimates. Improved emission estimates will be developed upon future availability of better emission inventory techniques and refined particle size data for these sources.

The estimated emissions from these fugitive dust sources are quite large. It is improper to assume that the air quality impact of these emissions is similarly significant. A major portion of the emissions from these sources consist of large particles which settle to the ground a short distance from the source. NEDS emission estimates include only estimated emissions of particles less than 30 micrometers in diameter, the maximum size particle that would be efficiently captured by standard particulate air quality sampling equipment. Available particle size data, particularly for entrainment of dust from paved roads, may overestimate the portion of particles under 30 micrometers in size. It should also be noted that since unpaved roads exist mainly in rural areas, that these emissions are spread over large land areas of low population density. These factors limit the impact on air quality of these sources.

Tabulated Data from NEDS

Nationwide emissions of the five criteria pollutants are summarized by emission source category in the first table (page 1) of this report. The second group of tables presents a summary of air pollutant emissions for individual States, intrastate AQCRs, and in the portions of interstate AQCRs within each State. Air pollutant emissions data for each interstate AQCR are presented in the third group of tables.

Each table has the same format, with emissions shown for each defined NEDS source category. Area-source categories are identical to those defined in the NEDS area-source file. The AEROS User's Manual (EPA-450/2-76-029) gives a detailed definition of each area source category. The following brief descriptions of selected area source categories are presented as additional clarifying information.

Area Source Category	Description
Gasoline-Light Duty Vehicles	Passenger vehicles (automobiles) with a gross weight less than 8500 pounds (3856 kg).
Gasoline-Light Duty Trucks	Gasoline powered cargo trucks with a gross weight less than 8500 pounds (3856 kg).
Gasoline-Heavy Duty Vehicles	Trucks and buses with a gross weight over 8500 pounds (3856 kg).
Off-highway	Off-highway vehicles include farm, construction, and industrial machinery, lawn and garden tractors, snowmobiles, and off-road motorcycles.
Gasoline Station Evaporation	This category represents evaporative emissions occurring at retail gasoline service stations from filling of underground storage tanks and vehicles tanks.

Area Source Category	Description
Forest Managed Burning	This category represents emissions from deliberate prescribed burning of forest and agricultural wastes as a standard management practice.
Frost Control	This category represents emissions from the use of orchard heaters.
Solvent Evaporation Loss	This category represents an estimate of evaporative emissions from organic solvent use, not accounted for by point sources in NEDS.

Point source data in the emissions summaries are grouped according to NEDS Source Classification Code (SCC) definitions. A complete listing is given in the AEROS Manual of Codes (EPA-450/2-76-005). A brief summary of the relationships between NEDS SCC categories and the emissions summary categories is given in the table on the next page.

Point Source Category	SCC	Description
External Combustion-Electric Generation	101	Power plant boiler fuel use
External Combustion-Industrial	102	Industrial boiler fuel use
External Combustion-Commercial-Institutional	103	Commercial-institutional boiler fuel use
Internal Combustion-Electric Generation	201	Power plant fuel use in turbines and reciprocating engines
Internal Combustion-Industrial	202	Industrial turbines and IC engines
Internal Combustion-Commercial-Institutional	203	Commercial-institutional turbines and IC engines
Internal Combustion-Engine Testing	204	Testing of aircraft and rocket engines
Industrial Process-Chemical Mfg.	301	Chemical production
Industrial Process-Food/Agriculture	302	Food and grain processing
Industrial Process-Primary Metal	303	Primary iron/steel, aluminum, copper, etc.
Industrial Process-Secondary Metal	304	Foundries, secondary metal smelting
Industrial Process-Mineral Products	305	Stone, clay, and glass
Industrial Process-Petroleum Industry	306, 310	Petroleum refining, natural gas processing
Industrial Process-Wood Products	307	Pulp and paper, plywood, and sawmills
Industrial Process-Organic Solvent Evaporation		Dry cleaning (401001), degreasing (401002), surface coating (402), graphic arts (405), and miscellaneous (490) point source organic solvent users
Industrial Process-Petroleum Storage/Transport		Storage of petroleum products (403, 404) and transportation and marketing losses (406)
Industrial Process-Metal Fabrication	309	Fabricated metal products
Industrial Process-Textile Mfg.	330	Fabrics and carpet operations
Industrial Process-Other/Not Classified		Industrial processes not identified above
Solid Waste Disposal	5	Municipal incinerators and open burning dumps (501), commercial incinerators and open burning (502) and industrial incinerators and open burning (503)

15. SUPPLEMENTARY NOTES

16. ABSTRACT

The National Emissions Report summarizes annual cumulative estimates of source emissions of five criteria pollutants: particulates, sulfur oxides, nitrogen oxides, volatile organic compounds, and carbon monoxide. Source emissions data are reported to the U.S. Environmental Protection Agency under provisions of Section 110 of the Clean Air Act, as amended 1977, and EPA Regulations, Title 40, Code of Federal Regulations, Part 51.321. Summary data are presented for the Nation as a whole, for individual States, and for Air Quality Control Regions and for individual interstate portions thereof.

The data compilations result from the operations of the National Emissions Data System (NEDS), which functions as a component of the comprehensive EPA air information system--the Aerometric and Emissions Reporting System (AEROS). AEROS is managed by the National Air Data Branch, Monitoring and Data Analysis Division, Office of Air Quality Planning and Standards, U.S. Environmental Protection Agency, at Research Triangle Park, North Carolina 27711.
